

1. A raw-time domain signal is a sequence of sampled amplitude values. Converting the sample into a spectrogram style feature compresses the sample and makes frequency extraction meaningful.
2. It is important because it is going from float32 to int8. This representation dataset is needed to calibrate the activations during this conversion.
3. It pulls preprocessed audio features.
4. `g_model` is a statically allocated byte array. `g_model_len` is so that the processor knows the boundary of this array.
- 5.
